**GEOMAGNETIC RADIOFLASH UNFOLD (GRUF)**

by

John S. Malik

**ABSTRACT**

A method of inverting the geomagnetic component of the radioflash signal from a nuclear explosion to obtain the gamma-ray time history was proposed by E. D. Dracott of the Atomic Weapons Research Establishment. A simplified development of an elaboration by B. R. Suydam has been programmed for small calculators in a form suitable for interim field analysis of such data. The development of the program is contained in the report.

**I. INTRODUCTION**

The most useful component of the radioflash signal emitted during a nuclear weapon explosion for diagnostic purposes is the geomagnetic component. As its name implies it results from the deflection of the Compton electrons, produced by interaction of gamma rays with air molecules, by the static geomagnetic field of the earth. It has the character of a magnetic dipole signal; the radiated electric field is perpendicular to the geomagnetic field. Its generation has been described in several reports, notably by Suydam.<sup>1</sup> Its potential for the determination of the gamma time history of the source producing the signal was recognized first by E. D. Dracott.<sup>2</sup> The implementation of the proposal has been by Moody and Hill<sup>3</sup> with further extension by Suydam.<sup>4</sup> Suydam's method has been implemented by Malik<sup>5</sup> in the Los Alamos Scientific Laboratory (LASL) program HMSD. Program GRUF is a simplified unfolding technique which has been programmed for the Wang 700 and Hewlett-Packard 9820 calculators; it is suitable for early data reduction while in the field. As in the development of the program HMSD,<sup>5</sup> the development of the program GRUF closely follows

Suydam's.<sup>4</sup>

**II. DEVELOPMENT**

The starting point is Maxwell's equations in MKS units:

$$\frac{\partial(\epsilon E)}{\partial t} + J_{Tot} = \text{curl}(B/\mu) \quad (1)$$

$$\frac{\partial B}{\partial t} = -\text{curl} E \quad (2)$$

In polar coordinates, the magnetic or TE set of equations is

$$\epsilon \frac{\partial E_{\theta}}{\partial t} + \sigma E_{\theta} = -J_{\theta} + \frac{1}{\mu r} \frac{\partial}{\partial r} (r B_{\theta}) - \frac{1}{\mu r} \frac{\partial B_r}{\partial \theta} \quad (3)$$

$$\frac{\partial B_r}{\partial t} = -\frac{1}{r} \sin \theta \frac{\partial}{\partial \theta} (\sin \theta E_{\theta}) \quad (4)$$

$$\frac{\partial B_{\theta}}{\partial t} = \frac{1}{r} \frac{\partial}{\partial r} (r E_{\theta}) \quad (5)$$

Transforming to retarded time coordinates:  $r' = r$ ,  $t' = t - r/c$ , for which the operators become  $\frac{\partial}{\partial r'} + \frac{\partial}{\partial r}$ ,  $-\frac{1}{c} \frac{\partial}{\partial t'}$ ,  $\frac{\partial}{\partial t} + \frac{\partial}{\partial t'}$  and dropping the prime on  $r$ , the  $B_{\theta}$  equation becomes:

*Ref*

$$\frac{\partial B_\theta}{\partial r} = \frac{1}{r} \frac{\partial (rE_\phi)}{\partial r} - \frac{1}{c} \frac{\partial E_\phi}{\partial t} \quad (6)$$

The  $B_\theta$  and  $B_r$  Eqs. (4) and (5) are integrable to

$$B_\theta = -\frac{1}{c} E_\phi + \frac{1}{r} \int \frac{\partial (rE_\phi)}{\partial r} dr \quad (7)$$

$$B_r = -\frac{1}{r} \sin\theta \int \frac{\partial (\sin\theta E_\phi)}{\partial \theta} d\theta \quad (8)$$

In the transformed coordinates, Eq. (3) becomes

$$c \frac{\partial E_\phi}{\partial r} + \sigma E_\phi = -J_\phi + \frac{1}{\mu r} \frac{\partial (rB_\theta)}{\partial r} - \frac{1}{\mu r} \frac{\partial B_r}{\partial \theta} - \frac{1}{\mu c} \frac{\partial B_\theta}{\partial t} \quad (9)$$

Substituting for  $B_r$  and  $B_\theta$  in Eq. (9),

$$\begin{aligned} \sigma E_\phi = & -J_\phi - \frac{1}{\mu c r} \frac{\partial (rE_\phi)}{\partial r} + \frac{1}{\mu r} \int \frac{\partial^2 (rE_\phi)}{\partial r^2} dr \\ & + \frac{1}{\mu} \sin\theta \frac{1}{r^2} \int \frac{\partial^2 (\sin\theta E_\phi)}{\partial \theta^2} d\theta \quad (10) \end{aligned}$$

By restricting the solutions to short times, the terms involving integrals may be dropped:

$$\frac{d(rE_\phi)}{dr} + \frac{1}{2} \sqrt{\frac{\mu}{c}} \sigma (rE_\phi) = -\frac{1}{2} \sqrt{\frac{\mu}{c}} (rJ_\phi) \quad (11)$$

This is the starting point for Suydam's development.

Choosing the polar axis antiparallel to the earth's magnetic field, the transverse current  $J_\phi$  at the azimuthal angle  $\theta$  is given by

$$J_\phi = \frac{\ell}{2a} J_C \sin\theta \quad (12)$$

where  $\ell$  is the range of the Compton electron,  $a$  the Larmor radius,  $J_C$  the Compton current. Equation (11) integrates to

$$(rE_\phi) = \frac{\ell}{2a} \sin\theta e^{-\chi} \int_0^r r E_\phi e^{-\chi} \frac{2_0}{2} \sigma dr \quad (13)$$

$$\text{with } E_\phi = -J_C / \sigma \quad (14)$$

$$\chi = \int_r^\infty \frac{2_0}{2} \sigma dr \quad (15)$$

$\ell$  = electron range

$a$  = Larmor radius

$$2_0 = \sqrt{\mu/\epsilon}$$

At large distances ( $\sigma \rightarrow 0$ ),  $\chi \rightarrow 0$  and

$$(rE_\phi) = \frac{\ell}{2a} \sin\theta \int_0^\infty r E_\phi e^{-\chi} \frac{2_0}{2} \sigma dr \quad (16)$$

Recognizing the azimuthal dependence, we will omit it temporarily and solve for  $rE_\phi$  at  $\theta = \pi/2$ . The gamma-ray dependent functions are approximated by

$$J_C = \frac{Y}{r^2} e^{-r/\lambda_T} f(r) \quad (17)$$

$$\sigma = \frac{\Gamma}{r^2} e^{-r/\lambda_A} g(r)$$

with

$$Y = \frac{e\ell}{4\pi\lambda_C W_Y} \quad (18)$$

$$\Gamma = \frac{e\mu_0}{4\pi\lambda_a W_{ip}}$$

where  $\mu_0$  is the electron mobility,  $W_{ip}$  is energy per ion pair,  $e$  the electron charge, and  $\lambda_C$ ,  $\lambda_a$  are  $\gamma$ -ray Compton and absorption mean free paths. The function  $g$  has dimensions of energy;  $f$ , that of energy/time. They are connected by the air-ion equation:

$$\frac{\partial g}{\partial t} + \beta g = f \quad (19)$$

where  $\beta$  is the electron attachment rate to

$Q_2$ : it is the only important loss rate for the times of interest. The electron mobility  $\mu_e$  is related to conductivity by  $\sigma = ne\mu_e$  with  $n$  being the electron density.

Denoting time derivatives by dot,  $E_S$  as defined by Eq. (14) becomes

$$E_S = \frac{YI}{Eg} = \frac{Y}{E} \left( \beta + \frac{\dot{g}}{g} \right) \quad (20)$$

writing the equation for  $rE_S$ , Eq. (16) as

$$rE_S = \frac{I}{2a} R_S E_S (1 + Q_m) \quad (21)$$

where  $R_S$  is the value of  $r$  satisfying

$$\frac{Z_0'}{Z_0} = -\frac{1}{\beta} \frac{\dot{\beta}}{\beta} \quad (22)$$

The correction quantity  $Q_m$  is tabulated by Suydam.<sup>4</sup> Equations (21) and (22) are general. Specializing  $J$  and  $\beta$  to Eqs. (17), Eq. (22) becomes

$$g(\cdot) = \frac{2\lambda_T}{Z_0} x(x+2) e^x \quad (23)$$

where

$$x = R_S \lambda_T \quad (24)$$

and  $\lambda_T$  is the  $\gamma$ -ray transport mean free path. By logarithmic differentiation:

$$\frac{\dot{g}}{g} = \left( 1 + \frac{2(x+1)}{x(x+2)} \right) \dot{x} \quad (25)$$

whence

$$E_S = \frac{Y}{E} \left\{ \beta + \dot{x} \left[ 1 + \frac{2(x+1)}{x(x+2)} \right] \right\} \quad (26)$$

The ratio  $Y/E$  is given by

$$\frac{Y}{E} = \frac{\frac{eI}{4\pi\lambda_c W_\gamma}}{\frac{2\pi e}{4\pi\lambda_c W_{ip}}} = \frac{\langle W_{ip} \lambda_a \rangle}{\mu_e W_\gamma \lambda_c} = \frac{I}{\mu_e} \quad (27)$$

where  $\nu$  is the number of secondary electrons produced per primary  $\gamma$ -ray of energy  $W_\gamma$ . Putting Eqs. (26) and (27) into Eq. (21),

$$rE_S = \frac{I}{2a} \cdot \frac{2\lambda_T}{\mu_e} x \left\{ \beta + \dot{x} \left[ 1 + \frac{2(x+1)}{x(x+2)} \right] \right\} (1+Q_m) \quad (28)$$

or

$$K_1 (rE_S) = x \left[ \beta + \dot{x} (1+\eta) \right] (1+Q_m) \quad (29)$$

with

$$K_1 = \frac{2a}{I} \cdot \frac{\mu_e}{\lambda_T} \cdot \frac{1}{\lambda_T} = \frac{2a}{I} \cdot \frac{W_\gamma \lambda_c}{W_{ip} \lambda_a} \frac{\mu_e}{I} \frac{1}{\lambda_T} \quad (30)$$

$$\eta = \frac{2(x+1)}{x(x+2)} \quad (31)$$

Equation (29) in the form

$$\dot{x} = \frac{K_1 (rE_S) / (1+Q_m) - \beta x}{x(1+\eta)} \quad (32)$$

gives the differential equation for  $x$  or  $R_S$ . Using Eq. (23) gives  $g(\cdot)$ . Combining Eqs. (20) and (21)

$$rE_S = \frac{I}{2a} \cdot \frac{\lambda_T Y}{E} \frac{f}{g} x(1+Q_m) \quad (33)$$

or

$$\begin{aligned} f &= \frac{2a}{I} \frac{I}{Y \lambda_T} \frac{(rE_S)}{(1+Q_m)} \frac{g}{x} \\ &= \frac{2a}{I} \cdot \frac{2}{Z_0 Y} \frac{(rE_S)}{(1+Q_m)} (x+2) e^x \\ &= K_3 \frac{(rE_S)}{(1+Q_m)} (x+2) e^x \end{aligned} \quad (34)$$

$$K_3 = \frac{4a}{Z_0} \frac{eI}{4\pi\lambda_c W_\gamma} = \frac{4a\lambda_c W_\gamma}{eI^2} \cdot \frac{4\pi}{Z_0} \quad (35)$$

$$K_2 = K_3/K_1 = \frac{2W_{ip} \lambda_a \lambda_T}{e\mu_e} \cdot \frac{4\pi}{Z_0} \quad (36)$$

From a measurement of  $rE_\phi$ , integration of Eq. (32) followed by a substitution into Eq. (34) yields the gamma-ray time dependence  $f$ . This assumes a knowledge of the other parameters in these relations, most of which are functions of the  $\gamma$ -ray energy. Since the source covers a spectrum of  $\gamma$ -ray energies from below 0.1 MeV to perhaps 10 MeV, a weighted average over the spectrum is needed. As the variable  $x = R/\lambda_T$  is not a linear function of distance, the averaged variables were fitted as functions of  $x$  rather than the radial distance. The electron mobility is approximated by

$$\mu_e = \frac{1.67 \times 10^{-9}}{(1+2p)(\rho/\rho_0)} \text{ m}^2/\text{v ns}$$

where  $p$  is the molecular per cent of water in the air. The electron attachment rate is approximated by

$$\beta = 0.09 \left( \frac{\rho}{\rho_0} \right)^2 \text{ ns}^{-1}$$

The correction factor for the integral is fit by

$$Q_m = (5.07 + 4.61x)/(1+16x+8.36x^2)$$

The quantity  $K_1$  as the result of the averaging is

$$K_1 = \frac{(0.189 + 0.0264x + 0.0141x^2)(\rho/\rho_0)^2}{6750(1 + 0.573x + 0.846x^2)(1+2p)} (\text{volt ns})^{-1}$$

$$K_3 = \frac{(0.47 + 0.094x^2)10^{17}(\rho/\rho_0)}{3000(1 + 0.78x^2)}$$

$$(\text{MeV volt ns})^{-1}$$

The measured vertical electric field,  $E_v$ , obtained at a distance  $R$  in meters co-altitude with the source at an azimuthal angle  $\theta$  and at a region where the dip angle is  $\psi$ , relates to the electric field  $rE_\phi$  in the

Eqs. (32) and (34) by

$$rE_\phi = RE_v / (\cos\psi \cdot \sin\theta)$$

The angle  $\theta$  is the supplement of the true bearing to the source minus the magnetic declination.

The integration is performed by a second order Rünge-Kutta scheme:

$$y_{i+1} = y_i + 0.5(p_1 + p_2) + 0(h^3)$$

$$p_1 = h \cdot f(x_i, y_i)$$

$$p_2 = h \cdot f(x_i + h, y_i + p_1)$$

$$f = y'$$

or in this instance:

$$p_1 = \Delta t \cdot \dot{x}(V_{i-1}, x_{i-1})$$

$$p_2 = \Delta t \cdot \dot{x}(V_i, x_{i-1} + p_1)$$

$$x_i = x_{i-1} + 0.5(p_1 + p_2)$$

where

$$\dot{x}(V, x) = \frac{K_1 V/Q - \beta x}{(2 + x + x^2)/(x+2)}$$
